# 3D Geometry Basics

## Coordinates of a point

- What is a point in space? How do we represent it?

# 3D Geometry Basics

## Coordinates of a point

- What is a point in space? How do we represent it?
- Cartesian coordinates  $(x, y, z)$

# 3D Geometry Basics

## Coordinates of a point

- What is a point in space? How do we represent it?
- Cartesian coordinates  $(x, y, z)$
- Reference frame  
 $global P = (0.1, 0.1, 0.0)$

# 3D Geometry Basics

## Coordinates of a point

- What is a point in space? How do we represent it?
- Cartesian coordinates  $(x, y, z)$
- Reference frame  
 $global P = (0.1, 0.1, 0.0)$
- Right-hand rule:  
 $(X, Y, Z) \rightarrow (R, G, B)$

# 3D Geometry Basics

## Coordinates of an object

- How do we represent an object in 3D?

# 3D Geometry Basics

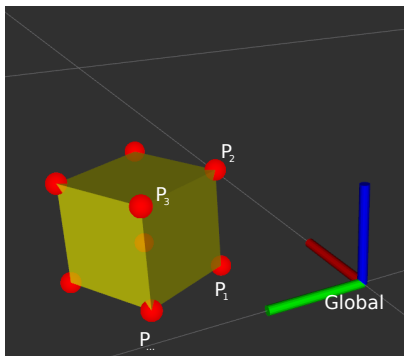

## Coordinates of an object

- How do we represent an object in 3D?
- What is an object?

# 3D Geometry Basics

## Coordinates of an object

- How do we represent an object in 3D?
- What is an object?
- Problem: all vertices change coordinates during movement

# 3D Geometry Basics

## Coordinates of an object

- How do we represent an object in 3D?
- What is an object?
- Problem: all vertices change coordinates during movement
- Solution: describe points on object relative to an object frame

$$global P_1 = (0.1, 0.1, 0.0)$$

$$box P_1 = (0.0, 0.0, 0.0)$$

# 3D Geometry Basics

## Coordinates of an object

- How do we represent an object in 3D?
- What is an object?
- Problem: all vertices change coordinates during movement
- Solution: describe points on object relative to an object frame

$$global P_1 = (0.1, 0.1, 0.0)$$

$$box P_1 = (0.0, 0.0, 0.0)$$

- What do we need to describe the object frame?

# 3D Geometry Basics

## Coordinates of a frame

- *box* has a position and orientation relative to *global*
- *position & orientation* together are called *pose*
- $global T_{box}$  is a transformation that transforms poses from *box* to *global*
- How do we represent position and orientation?

# Rotation Representations

There are 4 common ways to describe rotations:

- euler angles
- rotation matrix
- axis-angle
- quaternion

# Euler Angles

- Describes orientation using 3 angles:  
roll (x-rotation), pitch (y-rotation), yaw (z-rotation)

- Rotations are applied in sequence.

What is the sequence is defined through a convention.

There are many conventions, most common are z-y-x, x-y-z and z-x-z

# Euler Angles

## Pros/Cons

- + easy to interpret
- has a Gimbal lock problem
- not suited for interpolation
- there are many possible conventions, always make sure you know which one is used!

→ only useful for user interaction

# Euler Angles

## Gimbal lock

Loss of one degree of freedom, e.g. after  $90^\circ$  pitch (in this case red axis).

Coordinate Transformations

TF Library

ActionLib

Organizational

# Rotation Matrix

- $3 \times 3$  matrix  $R$
- is an orthogonal matrix, i.e.  $\det(R) = 1$  and  $R^{-1} = R^T$
- this means, all row (and correspondingly column) vectors are unit vectors, orthogonal to each other
- example:  $R = \begin{pmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{pmatrix}$  rotates about z-axis by  $\theta$

# Rotation Matrix Interpretation

- example:  $R = \begin{pmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{pmatrix}$   
rotates about z-axis by  $\theta$
- $global R_{box} = \begin{pmatrix} 0.88 & -0.48 & 0 \\ 0.48 & 0.88 & 0 \\ 0 & 0 & 1 \end{pmatrix}$
- columns are axis of `box` in the `global` coordinate frame

# Rotation Matrix

## Pros/Cons

- + easiest to do math with
  - rotate a vector with rotation matrix using matrix multiplication
  - rotation matrices can be combined using matrix multiplication
- + easy to construct rotation matrix from 3 vectors
- + can be extended to include translation in 4x4 matrix
- uses 9 numbers to describe 3 degrees of freedom
- matrix operations result in buildup of rounding error, you might have to normalize often
- not suitable for interpolation

# Axis-Angle

- any rotation can be represented as right hand rotation by  $\theta$  degree about a unit vector  $e$

- angle can be encoded in length of the vector

$$\begin{pmatrix} e_x \\ e_y \\ e_z \end{pmatrix}, \theta \rightarrow \begin{pmatrix} \theta e_x \\ \theta e_y \\ \theta e_z \end{pmatrix}$$

- can be rotated by rotation matrices using matrix multiplication

# Axis-Angle

## Pros/Cons

- math can get unstable when  $\theta$  is close to 0 or  $\pi$ , because there are infinitively many possible axis
- represents rotation by  $\theta$  differently from  $\theta + 2\pi$ , but it is the same rotation
- + easy interpolation, just scale the angle, but take into account that  $\theta = \theta + 2\pi$
- more useful when describing rotation differences/changes instead of orientations, found in ROS messages like Twist or Accel.

# Quaternion

- $q = (x, y, z, w)$
- number system introduced by Hamilton as an extension of complex numbers, only use case is representation of rotations
- only unit quaternions are used to represent rotations
- can be interpreted as an improved version of axis-angle

- $\begin{pmatrix} a_x \\ a_y \\ a_z \end{pmatrix}, \alpha \rightarrow \begin{pmatrix} a_x \cdot \sin(\alpha/2) \\ a_y \cdot \sin(\alpha/2) \\ a_z \cdot \sin(\alpha/2) \\ \cos(\alpha/2) \end{pmatrix}$

# Quaternion

## Pros/Cons

- + in contrast to axis-angle, stable when angle is close to zero and  $\pi$
  - + removes the  $\theta = \theta + 2\pi$  problem from axis-angle
  - + more compact representation than rotation matrices
  - + best for interpolation (slerp algorithm)
  - difficult to interpret
  - most useful for interpolation and describing orientations
- ROS standard for representing poses

# Rotations representations

## Conclusion

- use euler angles only on an interface level
- use axis-angle or quaternion for rigid body dynamics
- use quaternions when storing/sending orientation information or for interpolation
- else use rotation matrices for easy mathematical operations

# Homogeneous Transformations

- 4 x 4 matrix to represent pose transformations
- ${}_a T_b$  means transform from frame  $b$  to  $a$ , i.e.:  
 ${}_a T_b \cdot {}_b P = {}_a P$
- ${}_a T_b$  is the same as  ${}_a P_b$ , i.e. pose of origin of  $b$  in  $a$
- combined transformation:  
 ${}_c T_b \cdot {}_b T_a = {}_c T_a$
- invertible:  ${}_b T_a^{-1} = {}_a T_b$
- but  ${}_b T_a^{-1} \neq {}_b T_a^T$

$$\begin{pmatrix} \text{Rotation Matrix} & \begin{matrix} x \\ y \\ z \end{matrix} \\ \begin{matrix} r_{0,0} & r_{0,1} & r_{0,2} \\ r_{1,0} & r_{1,1} & r_{1,2} \\ r_{2,0} & r_{1,2} & r_{2,2} \end{matrix} & \begin{matrix} x \\ y \\ z \end{matrix} \\ \text{Fixed} & \begin{matrix} 0 & 0 & 0 \\ & & 1 \end{matrix} \end{pmatrix} \text{Translation}$$

# Homogeneous Transformation

- How do we do  ${}_c T_b \cdot {}_b P = {}_c P$ ?
- Append 1 to point  $P$ , before matrix multiplication:

$$\begin{pmatrix} r_{0,0} & r_{0,1} & r_{0,2} & x \\ r_{1,0} & r_{1,1} & r_{1,2} & y \\ r_{2,0} & r_{2,1} & r_{2,2} & z \\ 0 & 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} p_x \\ p_y \\ p_z \\ 1 \end{pmatrix} = \begin{pmatrix} r_{0,0}p_x + r_{0,1}p_y + r_{0,2}p_z + x \cdot 1 \\ r_{1,0}p_x + r_{1,1}p_y + r_{1,2}p_z + y \cdot 1 \\ r_{2,0}p_x + r_{2,1}p_y + r_{2,2}p_z + z \cdot 1 \\ 0p_x + 0p_y + 0p_z + 1 \cdot 1 \end{pmatrix}$$

# Homogeneous Transformation

- to transform  ${}_{box}P_2$  into the global frame  ${}_{global}P_2$ , multiply with  ${}_{global}T_{box}$
- ${}_{global}P_2 = {}_{global}T_{box} \cdot {}_{box}P_2$

# Homogeneous Transformation

- what is the pose of  $P_A$  in global coordinate frame:  $global P_A$ ?
- choose frame where it is the easiest to express a pose
- $box P_A = (0.05, 0.15, 0.05, 1.0)$
- $global P_A = global T_{box} \cdot box P_A$

# Homogeneous Transformation

$${}_{box}T_A = \begin{pmatrix} & 0.05 \\ & 0.15 \\ & 0.05 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

# Homogeneous Transformation

$${}_{box}T_A = \begin{pmatrix} 0 & -1 & 0 & 0.05 \\ 0 & 0 & -1 & 0.15 \\ 1 & 0 & 0 & 0.05 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

Coordinate Transformations

TF Library

ActionLib

Organizational

# Motivation

- Robots consist of many *parts* aka *links*
- Each link has its own *coordinate frame*
- Links change their position over time (including the robot base)
- Sensors measurements are defined in their own frame
- Example: transformations from camera to hand coordinates are needed for grasping objects

# Motivation

# Tracking Coordinate Frame Changes

- Transforms are produced by different nodes:
  - Localization node (AMCL, gmapping) for finding robot's pose in map
  - Odometry node (base driver) for tracking movement since initial pose
  - Joint positions (robot controllers and robot\_state\_publisher)
- Many publishers, many consumers
- Distributed system, redundancy issues, ...

- **TF**: a coordinate frame tracking system

# What is tf?

transform Library – a distributed coordinate frame tracking system

- Standardized protocol for publishing transforms to tf listeners
- Looking up and calculating transforms by asking tf listeners
- tf listener can be either local Lisp program or global tf buffer
- default global tf buffer is TF2's `buffer_server`
- ROS API for looking up, calculating and sending transforms
- Transforms are published on `/tf` and `/tf_static` topics:

`/tf`

- for all transforms that change over time
- publish with a fixed rate, even if transform didn't change

`/tf_static`

- assumed to be static, thus never outdated
- useful for reducing redundancy
- only publish once with latched flag

# TurtleSim TF

Launch the turtlesim TF demo:

```
$ roslaunch turtle_tf turtle_tf_demo.launch
```

# Utilities

- `view_frames`
- `tf_echo`
- `tf_monitor`
- `static_transform_publisher`
- `RViz`

# Utilities

## roslun tf view\_frames

Generate a TF tree graph:

```
$ roslun tf view_frames
```

- TF tree consists of frames (links) and the transforms between them.
- Each transform is cached (10 secs default caching time)
- Transforms must form a proper tree (no cycles)
- Can have disconnected trees, but you can only ask for transforms inside of the same tree

# Utilities

## tf\_echo

```
$ rosrn tf tf_echo <source_frame> <target_frame>
```

### tf\_echo

```
$ rosrn tf tf_echo turtle1 turtle2
At time 0.000
- Translation: [0.100, 0.100, 0.000]
- Rotation: in Quaternion [0.000, 0.000, 0.247, 0.969]
             in RPY (radian) [0.000, -0.000, 0.500]
             in RPY (degree) [0.000, -0.000, 28.648]
```

# Utilities

## static\_transform\_publisher

- `roslaunch tf2_ros static_transform_publisher x y z yaw pitch roll frame_id child_frame_id`  
or  
`roslaunch tf2_ros static_transform_publisher x y z qx qy qz qw frame_id child_frame_id`
- publishes *global*  $T_{box}$

## static\_transform\_publisher

```
$ roslaunch tf2_ros static_transform_publisher 0.1 0.1 0 3.14 0 0 global box
```

# Utilities

## tf\_monitor

- `roslaunch tf tf_monitor`

### tf\_monitor

```
$ roslaunch tf tf_monitor
RESULTS: for all Frames

Frames:
Frame: turtle1 published by /turtle1_tf_broadcaster Average Delay: 0.000382455 Max Delay: 0...
Frame: turtle2 published by /turtle2_tf_broadcaster Average Delay: 0.000267847 Max Delay: 0...

All Broadcasters:
Node: /turtle1_tf_broadcaster 64.6996 Hz, Average Delay: 0.000382455 Max Delay: 0.000991178
Node: /turtle2_tf_broadcaster 64.7127 Hz, Average Delay: 0.000267847 Max Delay: 0.00133464
```

# TF data types

- `frame_id`: name of the published frame
- `child_frame_id` has to be an existing frame
- `stamp`: time when this transform is valid
- `child_frame_id`  $T_{frame\_id}$

## tf2\_msgs/TFMessage

```
geometry_msgs/TransformStamped[]
transforms
  std_msgs/Header header
  uint32 seq
  time stamp
  string frame_id
  string child_frame_id
  geometry_msgs/Transform transform
  geometry_msgs/Vector3 translation
  float64 x
  float64 y
  float64 z
  geometry_msgs/Quaternion rotation
  float64 x
  float64 y
  float64 z
  float64 w
```

# TF and time

- tf buffers transforms for X seconds
- possible to lookup transforms from the past
- tf interpolates frames
- tf does not extrapolate! it can't see into the future

# Lisp TF

```
cl_tf
```

```
TF> (roslisp:start-ros-node "lisp_node")
TF> (defparameter *transform-listener*
      (make-instance 'transform-listener))
TF> (lookup-transform *transform-listener* :source-frame "turtle1"
                    :target-frame "turtle2")

#<STAMPED-TTRANSFORM
  FRAME-ID: "turtle1", CHILD-FRAME-ID: "turtle2", STAMP: 1.4169d9
  #<3D-VECTOR (0.0d0 0.0d0 0.0d0)>
  #<QUATERNION (0.0d0 0.0d0 -0.5401331068059835d0 0.8415796022552d0)>>
