# Intuition

```
$ roscore
$ rosrn interactive_marker_tutorials basic_controls
$ rosrn rviz rviz
```

The screenshot displays the RViz (Robot Visualization) interface. On the left, the 'Displays' panel is expanded to show 'InteractiveMarker' settings, including 'Update Topic' and 'Enable Transparency'. The central 3D view shows a robot's pose and trajectory in a 3D coordinate system. On the right, the 'Views' panel shows the current view type as 'Orbit (rviz)' and provides numerical data for 'Near Clip', 'Target Fov...', 'Distance', 'Yaw', 'Pitch', and 'Focal Point'. The status bar at the bottom shows ROS Time, ROS Elapsed, Wall Time, and Wall Elapsed.

# 3D Geometry Basics

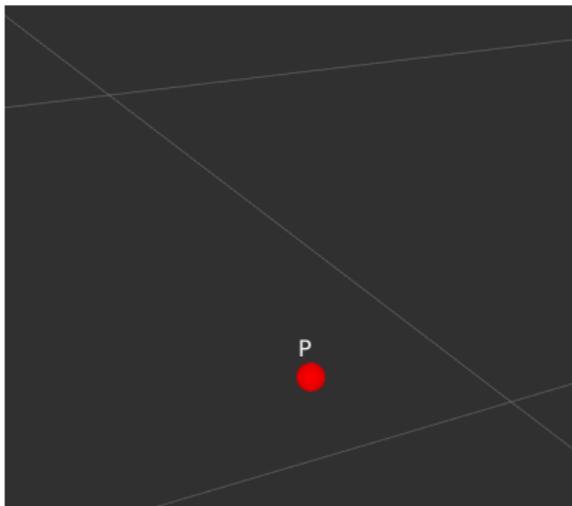

## Coordinates of a point

- What is a point in space? How do we represent it?

# 3D Geometry Basics

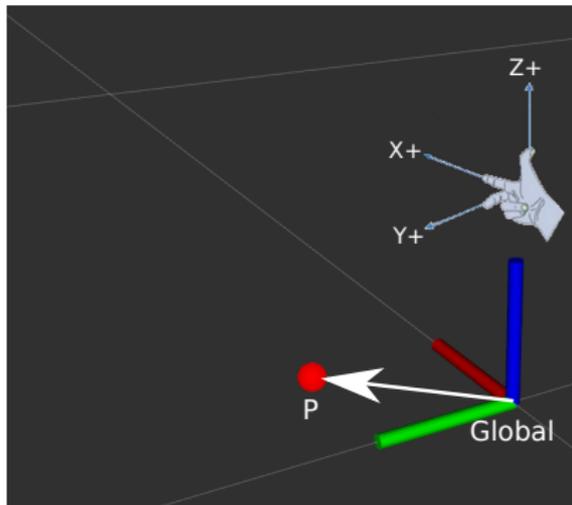

## Coordinates of a point

- What is a point in space? How do we represent it?
- Cartesian coordinates  $(x, y, z)$

# 3D Geometry Basics

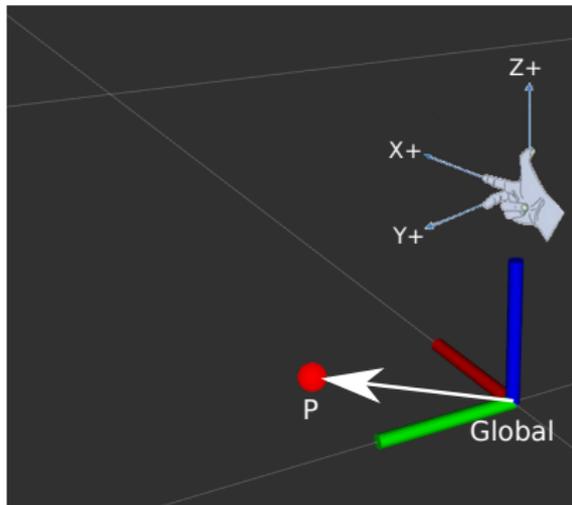

## Coordinates of a point

- What is a point in space? How do we represent it?
- Cartesian coordinates  $(x, y, z)$
- Reference frame  
 $global P = (0.1, 0.1, 0.0)$

# 3D Geometry Basics

## Coordinates of a point

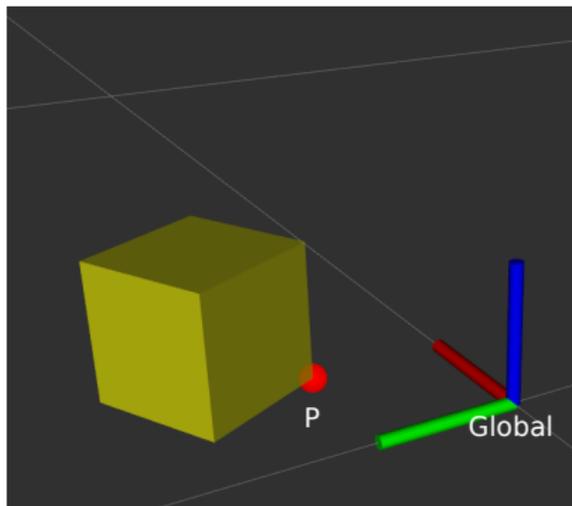

- What is a point in space? How do we represent it?
- Cartesian coordinates  $(x, y, z)$
- Reference frame  
 $global P = (0.1, 0.1, 0.0)$
- Right-hand rule:  
 $(X, Y, Z) \rightarrow (R, G, B)$

# 3D Geometry Basics

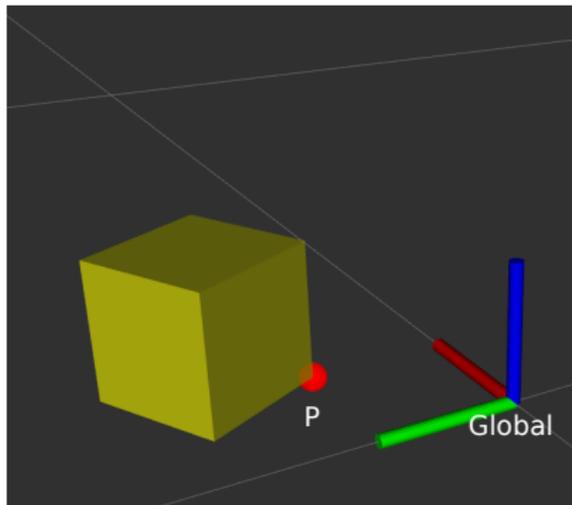

## Coordinates of an object

- How do we represent an object in 3D?

# 3D Geometry Basics

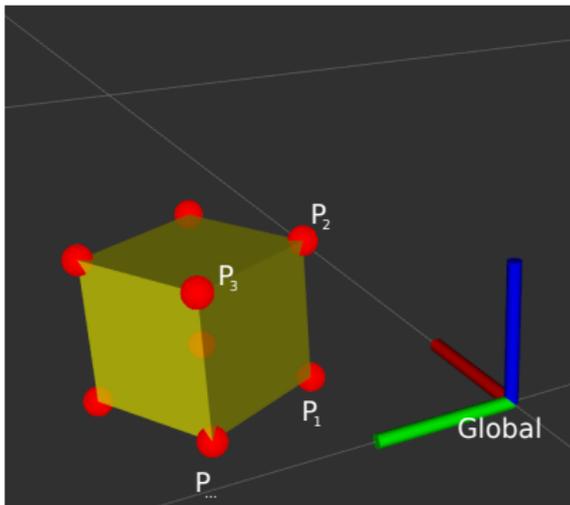

## Coordinates of an object

- How do we represent an object in 3D?
- What is an object?

# 3D Geometry Basics

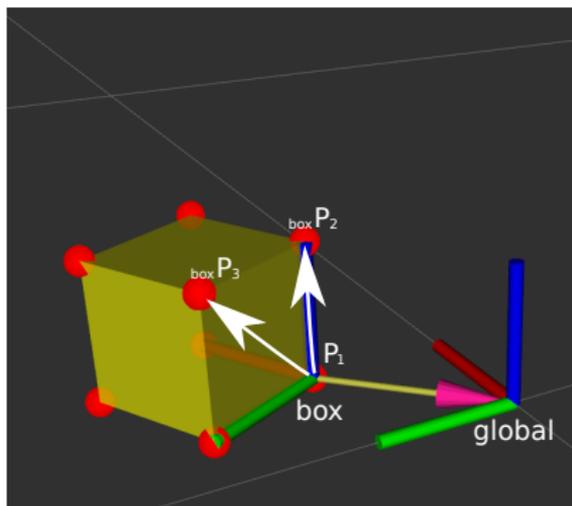

## Coordinates of an object

- How do we represent an object in 3D?
- What is an object?
- Problem: all vertices change coordinates during movement

# 3D Geometry Basics

## Coordinates of an object

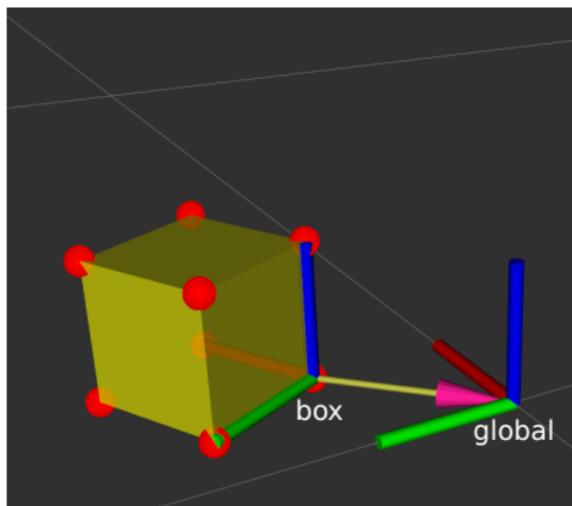

- How do we represent an object in 3D?
- What is an object?
- Problem: all vertices change coordinates during movement
- Solution: describe points on object relative to an object frame

$$global P_1 = (0.1, 0.1, 0.0)$$

$$box P_1 = (0.0, 0.0, 0.0)$$

# 3D Geometry Basics

## Coordinates of an object

- How do we represent an object in 3D?
- What is an object?
- Problem: all vertices change coordinates during movement
- Solution: describe points on object relative to an object frame

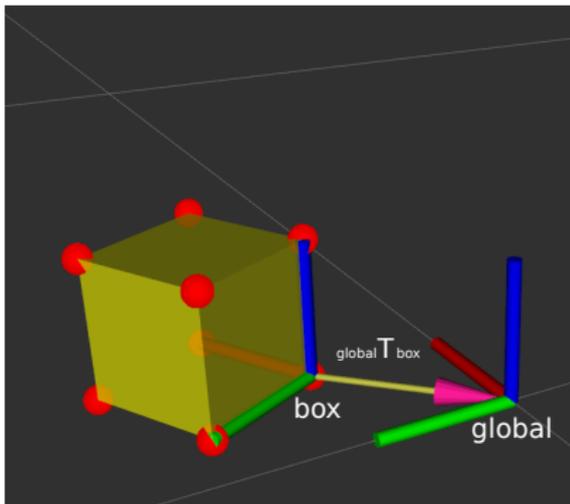

$$global P_1 = (0.1, 0.1, 0.0)$$

$$box P_1 = (0.0, 0.0, 0.0)$$

- What do we need to describe the object frame?

# 3D Geometry Basics

## Coordinates of a frame

- *box* has a position and orientation relative to *global*
- *position & orientation* together are called *pose*
- $global T_{box}$  is a transformation that transforms poses from *box* to *global*
- How do we represent position and orientation?

# Rotation Representations

There are 4 common ways to describe rotations:

- euler angles
- rotation matrix
- axis-angle
- quaternion

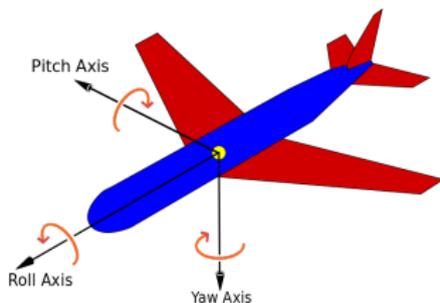

# Euler Angles

- Describes orientation using 3 angles:  
roll (x-rotation), pitch (y-rotation), yaw (z-rotation)

- Rotations are applied in sequence.

What is the sequence is defined through a convention.

There are many conventions, most common are z-y-x, x-y-z and z-x-z

# Euler Angles

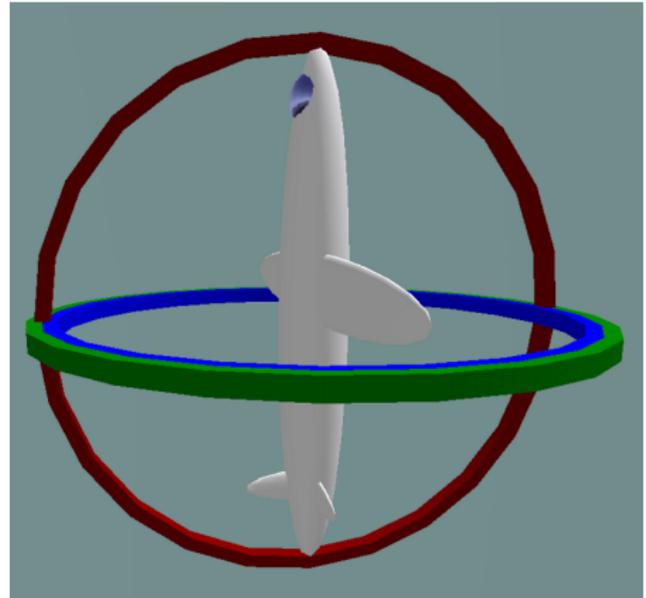

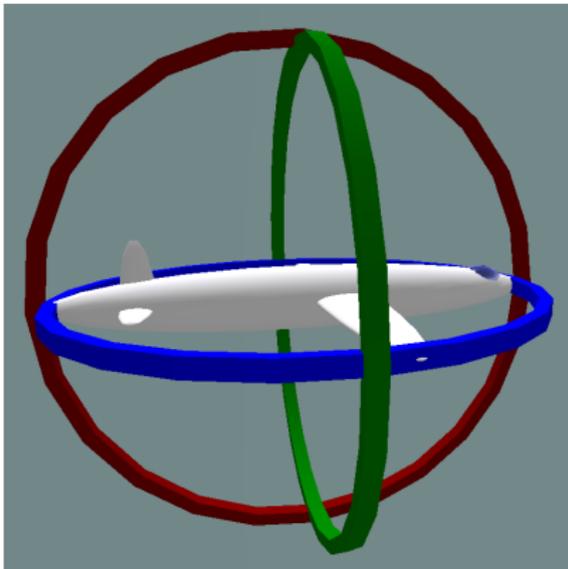

## Pros/Cons

- + easy to interpret
  - has a Gimbal lock problem
  - not suited for interpolation
  - there are many possible conventions, always make sure you know which one is used!
- only useful for user interaction

# Euler Angles

## Gimbal lock

Loss of one degree of freedom, e.g. after  $90^\circ$  pitch (in this case red axis).

ActionLib

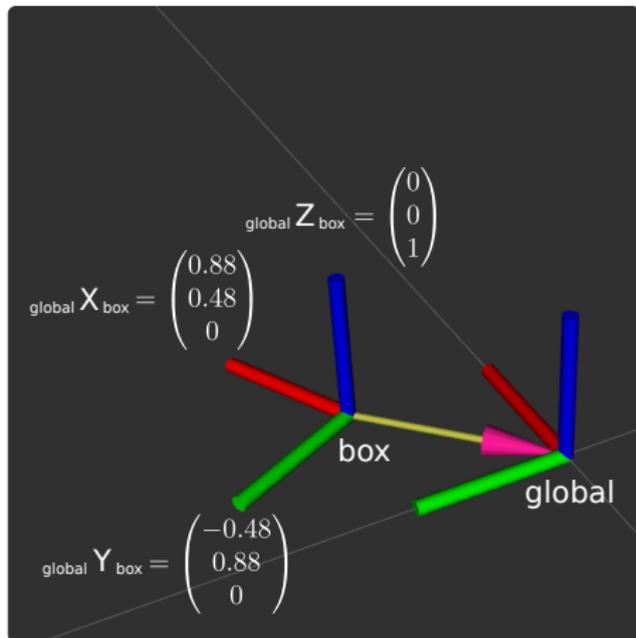

Organizational

# Rotation Matrix

- 3 x 3 matrix  $R$
- is an orthogonal matrix, i.e.  $\det(R) = 1$  and  $R^{-1} = R^T$
- this means, all row (and correspondingly column) vectors are unit vectors, orthogonal to each other
- example:  $R = \begin{pmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{pmatrix}$  rotates about z-axis by  $\theta$

# Rotation Matrix Interpretation

- example:  $R = \begin{pmatrix} \cos(\theta) & -\sin(\theta) & 0 \\ \sin(\theta) & \cos(\theta) & 0 \\ 0 & 0 & 1 \end{pmatrix}$   
rotates about z-axis by  $\theta$
- $global R_{box} = \begin{pmatrix} 0.88 & -0.48 & 0 \\ 0.48 & 0.88 & 0 \\ 0 & 0 & 1 \end{pmatrix}$
- columns are axis of `box` in the `global` coordinate frame

# Rotation Matrix

## Pros/Cons

- + easiest to do math with
  - rotate a vector with rotation matrix using matrix multiplication
  - rotation matrices can be combined using matrix multiplication
- + easy to construct rotation matrix from 3 vectors
- + can be extended to include translation in 4x4 matrix
- uses 9 numbers to describe 3 degrees of freedom
- matrix operations result in buildup of rounding error, you might have to normalize often
- not suitable for interpolation

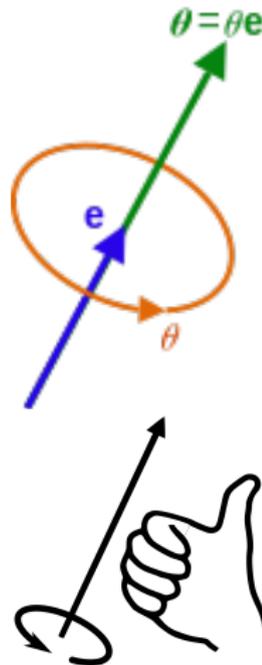

# Axis-Angle

- any rotation can be represented as right hand rotation by  $\theta$  degree about a unit vector  $e$

- angle can be encoded in length of the vector

$$\begin{pmatrix} e_x \\ e_y \\ e_z \end{pmatrix}, \theta \rightarrow \begin{pmatrix} \theta e_x \\ \theta e_y \\ \theta e_z \end{pmatrix}$$

- can be rotated by rotation matrices using matrix multiplication

# Axis-Angle

## Pros/Cons

- math can get unstable when  $\theta$  is close to 0 or  $\pi$ , because there are infinitively many possible axis
- represents rotation by  $\theta$  differently from  $\theta + 2\pi$ , but it is the same rotation
- + easy interpolation, just scale the angle, but take into account that  $\theta = \theta + 2\pi$
- more useful when describing rotation differences/changes instead of orientations, found in ROS messages like Twist or Accel.

# Quaternion

- $q = (x, y, z, w)$
- number system introduced by Hamilton as an extension of complex numbers, only use case is representation of rotations
- only unit quaternions are used to represent rotations
- can be interpreted as an improved version of axis-angle

- $\begin{pmatrix} a_x \\ a_y \\ a_z \end{pmatrix}, \alpha \rightarrow \begin{pmatrix} a_x \cdot \sin(\alpha/2) \\ a_y \cdot \sin(\alpha/2) \\ a_z \cdot \sin(\alpha/2) \\ \cos(\alpha/2) \end{pmatrix}$

# Quaternion

## Pros/Cons

- + in contrast to axis-angle, stable when angle is close to zero and  $\pi$
  - + removes the  $\theta = \theta + 2\pi$  problem from axis-angle
  - + more compact representation than rotation matrices
  - + best for interpolation (slerp algorithm)
  - difficult to interpret
  - most useful for interpolation and describing orientations
- ROS standard for representing poses

# Rotations representations

## Conclusion

- use euler angles only on an interface level
- use axis-angle or quaternion for rigid body dynamics
- use quaternions when storing/sending orientation information or for interpolation
- else use rotation matrices for easy mathematical operations

# Homogeneous Transformations

- 4 x 4 matrix to represent pose transformations
- ${}_aT_b$  means transform from frame  $b$  to  $a$ , i.e.:  
 ${}_aT_b \cdot {}_bP = {}_aP$
- ${}_aT_b$  is the same as  ${}_aP_b$ , i.e. pose of origin of  $b$  in  $a$
- combined transformation:  
 ${}_cT_b \cdot {}_bT_a = {}_cT_a$
- invertible:  ${}_bT_a^{-1} = {}_aT_b$
- but  ${}_bT_a^{-1} \neq {}_bT_a^T$

$$\begin{array}{c}
 \text{Rotation Matrix} \\
 \left( \begin{array}{ccc|c}
 r_{0,0} & r_{0,1} & r_{0,2} & x \\
 r_{1,0} & r_{1,1} & r_{1,2} & y \\
 r_{2,0} & r_{1,2} & r_{2,2} & z \\
 \hline
 0 & 0 & 0 & 1
 \end{array} \right) \begin{array}{l} \\ \\ \\ \text{Translation} \end{array} \\
 \text{Fixed}
 \end{array}$$

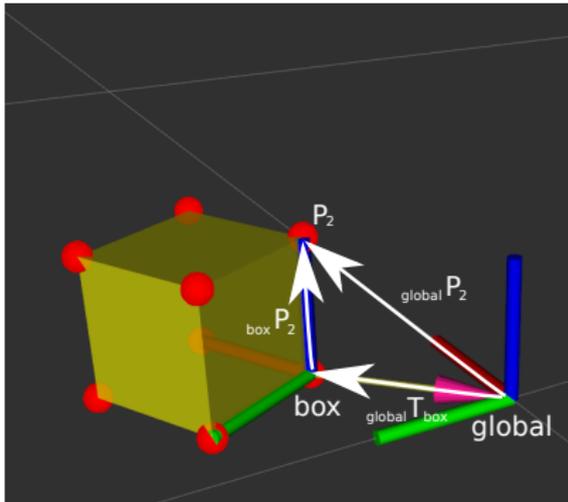

# Homogeneous Transformation

- How do we do  ${}_c T_b \cdot {}_b P = {}_c P$ ?
- Append 1 to point  $P$ , before matrix multiplication:

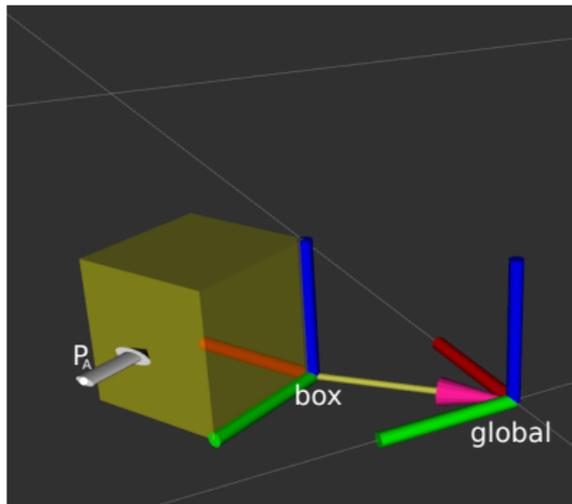

$$\begin{pmatrix} r_{0,0} & r_{0,1} & r_{0,2} & x \\ r_{1,0} & r_{1,1} & r_{1,2} & y \\ r_{2,0} & r_{2,1} & r_{2,2} & z \\ 0 & 0 & 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} p_x \\ p_y \\ p_z \\ 1 \end{pmatrix} = \begin{pmatrix} r_{0,0}p_x + r_{0,1}p_y + r_{0,2}p_z + x \cdot 1 \\ r_{1,0}p_x + r_{1,1}p_y + r_{1,2}p_z + y \cdot 1 \\ r_{2,0}p_x + r_{2,1}p_y + r_{2,2}p_z + z \cdot 1 \\ 0p_x + 0p_y + 0p_z + 1 \cdot 1 \end{pmatrix}$$

# Homogeneous Transformation

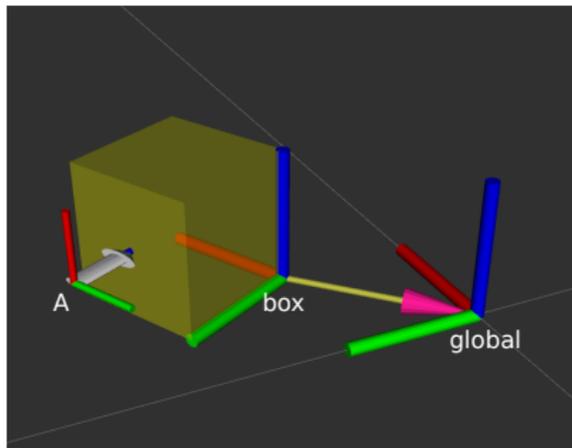

- to transform  ${}_{box}P_2$  into the global frame  ${}_{global}P_2$ , multiply with  ${}_{global}T_{box}$
- ${}_{global}P_2 = {}_{global}T_{box} \cdot {}_{box}P_2$

# Homogeneous Transformation

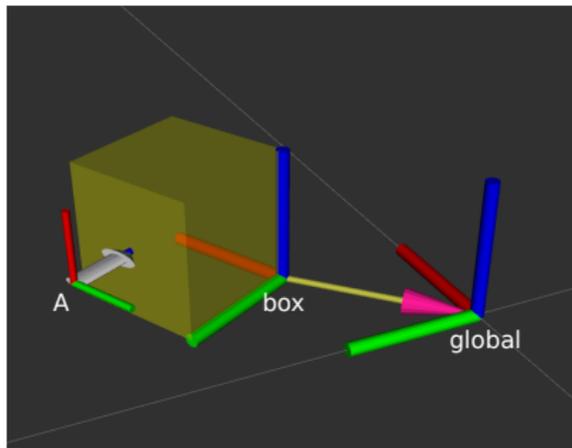

- what is the pose of  $P_A$  in global coordinate frame:  $global P_A$ ?
- choose frame where it is the easiest to express a pose
- $box P_A = (0.05, 0.15, 0.05, 1.0)$
- $global P_A = global T_{box} \cdot box P_A$

# Homogeneous Transformation

$${}_{box}T_A = \begin{pmatrix} & & & 0.05 \\ & & & 0.15 \\ & & & 0.05 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

# Homogeneous Transformation

$${}_{box}T_A = \begin{pmatrix} 0 & -1 & 0 & 0.05 \\ 0 & 0 & -1 & 0.15 \\ 1 & 0 & 0 & 0.05 \\ 0 & 0 & 0 & 1 \end{pmatrix}$$

# Points in ROS Lisp

Point in 3D:  $\{x, y, z\}$

## 3D-Vector

```
CL-TRANSFORMS> (make-3d-vector 1 2 3)
#<3D-VECTOR (1.0d0 2.0d0 3.0d0)>

# Rotations in ROS Lisp

Axis-Angle representation:

$$\langle \text{axis}, \text{angle} \rangle = \left\langle \begin{bmatrix} a_x \\ a_y \\ a_z \end{bmatrix}, \theta \right\rangle$$

Axis-Angle  $\rightarrow$  Quaternion:

$$Q = \begin{pmatrix} q_x \\ q_y \\ q_z \\ q_w \end{pmatrix} = \begin{pmatrix} a_x \sin(\theta/2) \\ a_y \sin(\theta/2) \\ a_z \sin(\theta/2) \\ \cos(\theta/2) \end{pmatrix}$$

## 3D-Vector

```
CL-TRANSFORMS> (make-quaternion 0 0 0 1)
CL-TRANSFORMS> (describe *)
#<QUATERNION (0.0d0 0.0d0 0.0d0 1.0d0)>
[standard-object]
Slots with :INSTANCE allocation:
  X = 0.0d0
  Y = 0.0d0
  Z = 0.0d0
  W = 1.0d0
CL-TRANSFORMS> (axis-angle->quaternion
                  (make-3d-vector 0.0 0.1) pi)
```

# Poses in ROS Lisp

## cl-transforms:pose

```
CL-TRANSFORMS> (setf p (make-pose
                        (make-3d-vector 1 2 0)
                        (make-quaternion 0 0 0 1)))

#<POSE
  #<3D-VECTOR (1.0d0 2.0d0 0.0d0)>
  #<QUATERNION (0.0d0 0.0d0 0.0d0 1.0d0)>>
CL-TRANSFORMS> (origin p)
#<3D-VECTOR (1.0d0 2.0d0 0.0d0)>
CL-TRANSFORMS> (orientation p)
#<QUATERNION (0.0d0 0.0d0 0.0d0 1.0d0)>
```

# Motivation

- Robots consist of many *parts* aka *links*
- Each link has its own *coordinate frame*
- Links change their position over time (including the robot base)
- Sensors measurements are defined in their own frame
- Example: transformations from camera to hand coordinates are needed for grasping objects

# Motivation

# Tracking Coordinate Frame Changes

- Transforms are produced by different nodes:
  - Localization node (AMCL, gmapping) for finding robot's pose in map
  - Odometry node (base driver) for tracking movement since initial pose
  - Joint positions (robot controllers and robot\_state\_publisher)
- Many publishers, many consumers
- Distributed system, redundancy issues, ...

- **TF**: a coordinate frame tracking system

# What is tf?

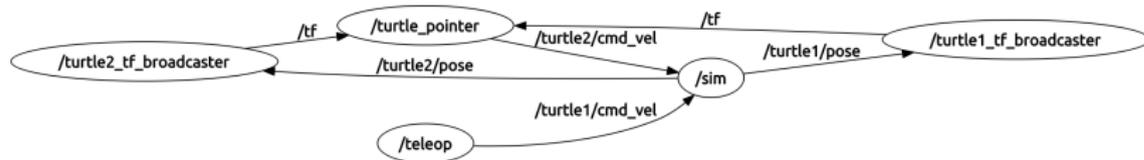

transform Library – a distributed coordinate frame tracking system

- Standardized protocol for publishing transforms to tf listeners
- Looking up and calculating transforms by asking tf listeners
- tf listener can be either local Lisp program or global tf buffer
- default global tf buffer is TF2's `buffer_server`
- ROS API for looking up, calculating and sending transforms
- Transforms are published on `/tf` and `/tf_static` topics:
  - `/tf`
    - for all transforms that change over time
    - publish with a fixed rate, even if transform didn't change
  - `/tf_static`
    - assumed to be static, thus never outdated
    - useful for reducing redundancy
    - only publish once with latched flag

# TurtleSim TF

Launch the turtlesim TF demo:

```
$ roslaunch turtle_tf turtle_tf_demo.launch
```

# Utilities

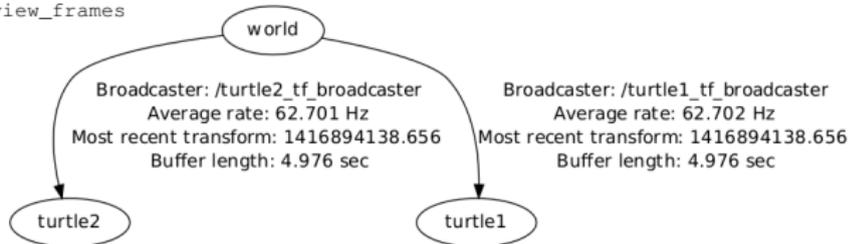

- `view_frames`
- `tf_echo`
- `tf_monitor`
- `static_transform_publisher`
- `RViz`

# Utilities

## roslun tf view\_frames

Generate a TF tree graph:

```
$ roslun tf view_frames
```

- TF tree consists of frames (links) and the transforms between them.
- Each transform is cached (10 secs default caching time)
- Transforms must form a proper tree (no cycles)
- Can have disconnected trees, but you can only ask for transforms inside of the same tree

# Utilities

## tf\_echo

```
$ rosrun tf tf_echo <source_frame> <target_frame>
```

### tf\_echo

```
$ rosrun tf tf_echo turtle1 turtle2
At time 0.000
- Translation: [0.100, 0.100, 0.000]
- Rotation: in Quaternion [0.000, 0.000, 0.247, 0.969]
             in RPY (radian) [0.000, -0.000, 0.500]
             in RPY (degree) [0.000, -0.000, 28.648]
```

# Utilities

## `static_transform_publisher`

- `roslaunch tf2_ros static_transform_publisher x y z yaw pitch roll frame_id child_frame_id`  
or  
`roslaunch tf2_ros static_transform_publisher x y z qx qy qz qw frame_id child_frame_id`
- publishes  $global T_{box}$

## `static_transform_publisher`

```
$ roslaunch tf2_ros static_transform_publisher 0.1 0.1 0 3.14 0 0 global box
```

# Utilities

## tf\_monitor

- `roslaunch tf tf_monitor`

### tf\_monitor

```
$ roslaunch tf tf_monitor
RESULTS: for all Frames

Frames:
Frame: turtle1 published by /turtle1_tf_broadcaster Average Delay: 0.000382455 Max Delay: 0...
Frame: turtle2 published by /turtle2_tf_broadcaster Average Delay: 0.000267847 Max Delay: 0...

All Broadcasters:
Node: /turtle1_tf_broadcaster 64.6996 Hz, Average Delay: 0.000382455 Max Delay: 0.000991178
Node: /turtle2_tf_broadcaster 64.7127 Hz, Average Delay: 0.000267847 Max Delay: 0.00133464
```

# TF data types

- `frame_id`: name of the published frame
- `child_frame_id` has to be an existing frame
- `stamp`: time when this transform is valid
- `child_frame_id`  $T_{frame\_id}$

## tf2\_msgs/TFMessage

```
geometry_msgs/TransformStamped[]
transforms
std_msgs/Header header
uint32 seq
time stamp
string frame_id
string child_frame_id
geometry_msgs/Transform transform
geometry_msgs/Vector3 translation
float64 x
float64 y
float64 z
geometry_msgs/Quaternion rotation
float64 x
float64 y
float64 z
float64 w
```

# TF and time

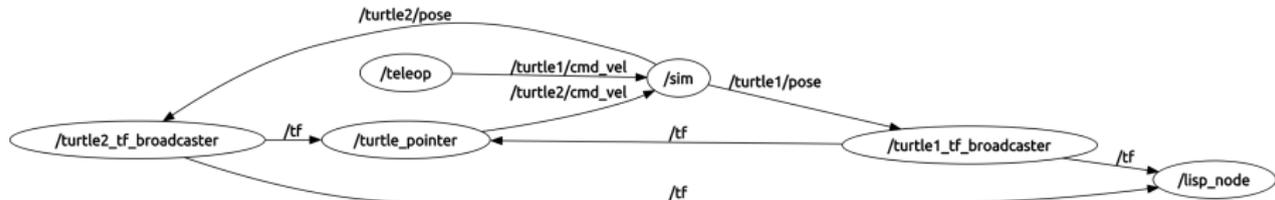

- tf buffers transforms for X seconds
- possible to lookup transforms from the past
- tf interpolates frames
- tf does not extrapolate! it can't see into the future

# Lisp TF

```
cl_tf
```

```
TF> (roslisp:start-ros-node "lisp_node")
TF> (defparameter *transform-listener*
      (make-instance 'transform-listener))
TF> (lookup-transform *transform-listener* :source-frame "turtle1"
                       :target-frame "turtle2")

#<STAMPED-TTRANSFORM
